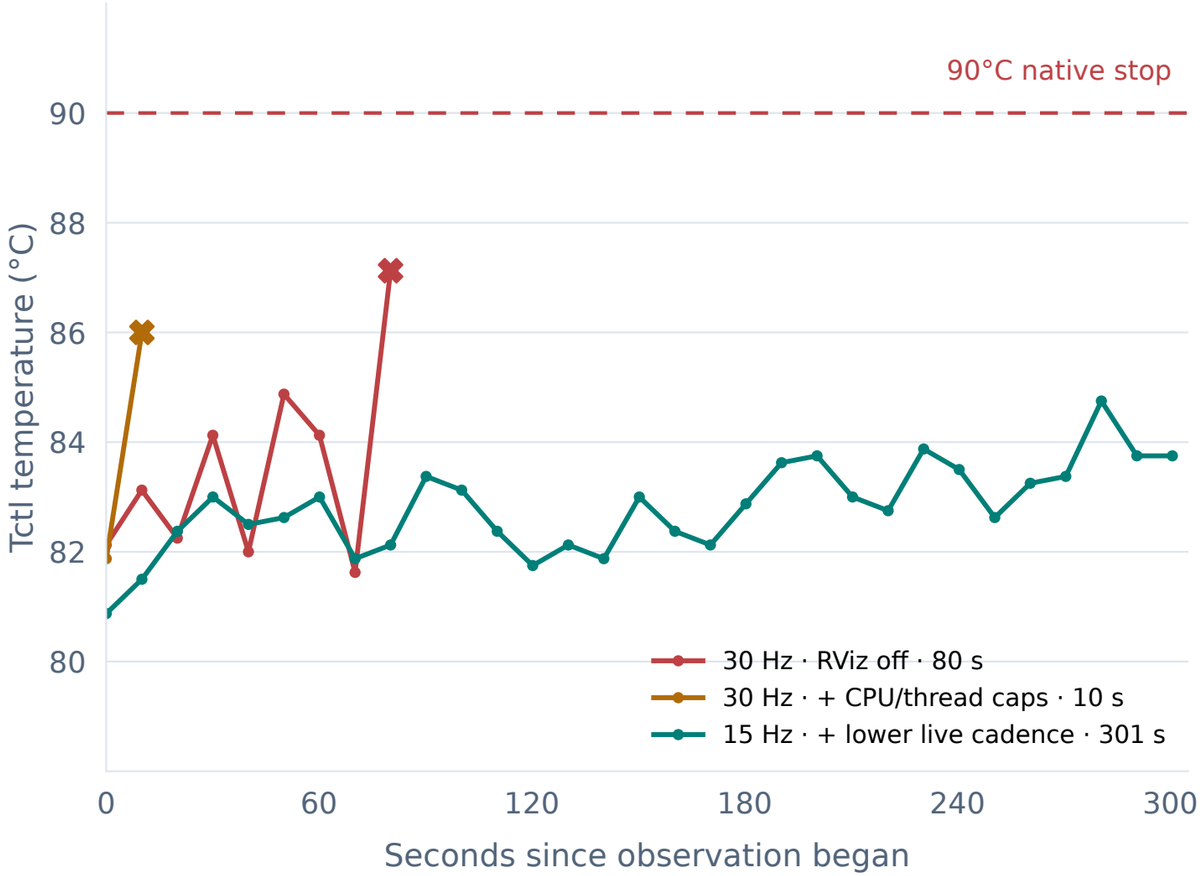
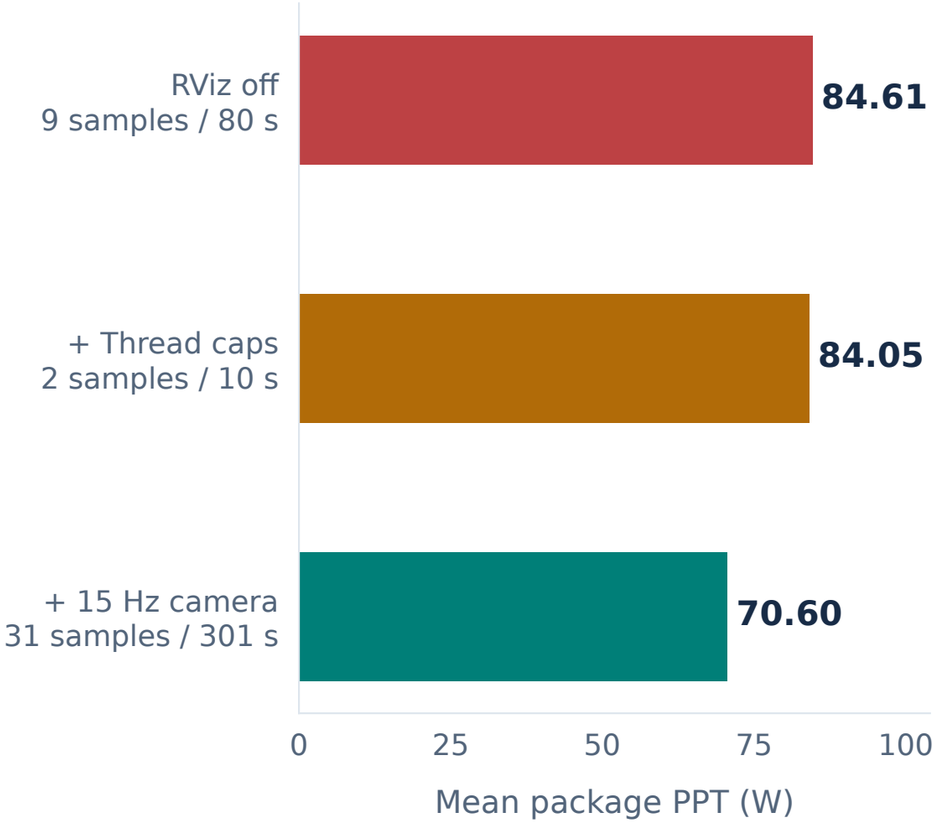
Thermal repair: measured iteration results

Removing RViz alone and limiting CPU threads still led to early thermal verification stops.

Saved temperature readings



Observed package power



Final stationary interval: 70.60 W mean package power; 84.75°C peak.

Separate runs with different starting temperatures, motion and durations. The 10 s thread-cap interval contains only two samples.

Early observers stopped at ≥85°C on sampled checks; native protection stayed at 90°C. These are observed intervals, not a controlled performance benchmark.
